Extending Acyclicity Notions for Existential Rules  
(long version)

Jean-François Baget\textsuperscript{1} and Fabien Garreau\textsuperscript{2} and Marie-Laure Mugnier\textsuperscript{3} and Swan Rocher\textsuperscript{3}

This report contains a revised version (July 2014) of the paper that will appear in the proceedings of ECAI 2014 and an appendix with proofs that could not be included in the paper for space restriction reasons.

Abstract. Existential rules have been proposed for representing ontological knowledge, specifically in the context of Ontology-Based Query Answering. Entailment with existential rules is undecidable. We focus in this paper on conditions that ensure the termination of a breadth-first forward chaining algorithm known as the chase. First, we propose a new tool that allows to extend existing acyclicity conditions ensuring chase termination, while keeping good complexity properties. Second, we consider the extension to existential rules with nonmonotonic negation under stable model semantics and further extend acyclicity results obtained in the positive case.

1 INTRODUCTION

Ontology-Based Query Answering is a new paradigm in data management, which aims to exploit ontological knowledge when accessing data. Existential rules have been proposed for representing ontological knowledge, specifically in this context \cite{baget2007}. These rules allow to assert the existence of unknown individuals, an essential feature in an open-domain perspective. They generalize lightweight description logics, such as DL-Lite and $\mathcal{EL}$ \cite{miben2006} and overcome some of their limitations by allowing any predicate arity as well as cyclic structures.

In this paper, we focus on a breadth-first forward chaining algorithm, known as the chase in the database literature \cite{barto1991}. The chase was originally used in the context of very general database constraints, called tuple-generating dependencies, which have the same logical form as existential rules \cite{baget2007}.

Given a knowledge base composed of data and existential rules, the chase triggers the rules and materializes performed inferences in the data. The “saturated” data can then be queried like a classical database. This allows to benefit from optimizations implemented in current data management systems. However, the chase is not ensured to terminate—which applies to any sound and complete mechanism, since entailment with existential rules is undecidable \cite{baget2007}. Various acyclicity notions ensuring chase termination have been proposed in knowledge representation and database theory.

Paper contributions. We generalize known acyclicity conditions, first, for plain existential rules, second, for their extension to nonmonotonic negation with stable semantics.

1. Plain existential rules. Acyclicity conditions found in the literature can be classified into two main families: the first one constrains the way existential variables are propagated during the chase, e.g., \cite{clark1994,bluthe2008,frascardo2011}, and the second one constrains dependencies between rules, i.e., the fact that a rule may lead to trigger another rule, e.g., \cite{baget2007}. These conditions are based on different graphs, but all of them can be seen as forbidding “dangerous” cycles in the considered graph. We define a new family of graphs that allows to unify and strictly generalize these acyclicity notions, without increasing worst-case complexity.

2. Extension to nonmonotonic negation. Nonmonotonic negation is a useful feature in ontology modeling. Nonmonotonic extensions to existential rules were recently considered in \cite{baget2007} with stratified negation, \cite{etzold2012} with well-founded semantics and \cite{clark2012} with stable model semantics. The latter paper focuses on cases where a unique finite model exists; we consider the same rule framework, however without enforcing a unique model. We further extend acyclicity results obtained on positive rules by exploiting negative information as well.

The paper is organized according to these two issues.

2 PRELIMINARIES

An atom is of the form $p(t_1, \ldots, t_k)$ where $p$ is a predicate of arity $k$ and the $t_i$ are terms, i.e., variables or constants. An atomset is a finite set of atoms. If $F$ is an atom or an atomset, we denote by $\text{terms}(F)$ (resp. $\text{vars}(F)$) the set of terms (resp. variables) that occur in $F$. In the examples illustrating the paper, all the terms are variables (denoted by $x$, $y$, $z$, etc.), unless otherwise specified. Given atomsets $A_1$ and $A_2$, a homomorphism $h$ from $A_1$ to $A_2$ is a substitution of $\text{vars}(A_1)$ by $\text{terms}(A_2)$ such that $h(A_1) \subseteq A_2$.

An existential rule (and simply a rule hereafter) is of the form $R = \forall x \exists y (B \rightarrow \exists z H)$, where $B$ and $H$ are conjunctions of atoms, with $\text{vars}(B) = \bar{x} \cup \bar{y}$ and $\text{vars}(H) = \bar{x} \cup \bar{z}$. $B$ and $H$ are respectively called the body and the head of $R$. We also use the notations $\text{body}(R)$ for $B$ and $\text{head}(R)$ for $H$. Variables $\bar{x}$, which appear in both $B$ and $H$, are called frontier variables. Variables $\bar{z}$, which appear only in $H$, are called existential variables. Hereafter, we omit quantifiers in rules as there is no ambiguity. E.g., $p(x,y) \rightarrow p(y,z)$ stands for $\forall x \forall y (p(x,y) \rightarrow \exists z (p(y,z)))$.

An existential rule with an empty body is called a fact. A fact is thus an existentially closed conjunction of atoms. A Boolean conjunctive query (BCQ) has the same form. A knowledge base $\mathcal{K} = (F, \mathcal{R})$ is composed of a finite set of facts (which is seen as a single fact) $F$ and a finite set of existential rules $\mathcal{R}$. The fundamen-
Theorem 3.1 (Existential Variability) Let \( R \) be a rule. Then \( R \) is existentially variably if and only if there exists a \( p \)-position \( x \) in \( R \) such that \( x \) is the head variable of \( R \) and \( x \) is not in the body of \( R \).

3.2 Rule dependency-based approach

In the second approach, the aim is to avoid cyclic triggering of rules. We say that a rule \( R_2 \) depends on a rule \( R_1 \) if an application of \( R_1 \) may lead to a new application of \( R_2 \); there exists an atom set \( F \) such that for any \( R \) with \( \text{head}(R) \subseteq F \) and \( R \) is applicable to \( F \) with homomorphism \( \pi \) and \( R_2 \) is applicable to \( F' \) = \( \alpha(F, R_1, \pi) \) with homomorphism \( \pi' \), which is new (\( \pi' \) is not a homomorphism to \( F \)) and useful (\( \pi' \) cannot be extended to a homomorphism from \( F_2 \) to \( F' \)). This abstract dependency relation can be computed with a unification operation known as piece-unifier \( \alpha \). Piece-unification takes existential variables into account, hence is more complex than the usual unification between atoms. A piece-unifier of a rule body \( B_2 \) with a rule head \( H_1 \) is a substitution \( \mu \) of \( \text{vars}(B_2) \cup \text{vars}(H_1) \), where \( B_2' \subseteq B_2 \) and \( H_1' \subseteq H_1 \), such that: (1) \( \mu(B_2) = \mu(H_1') \), and (2) existential variables in \( H_1' \) are not unified with separating variables of \( B_2' \), i.e., variables that occur both in \( B_2' \) and in \( B_2 \setminus B_2' \); in other words, if a variable \( x \) occurring in \( B_2' \) is unified with an existential variable \( y \) in \( H_1' \), then all atoms in which \( x \) occur also belong to \( B_2' \). It holds that \( R_2 \) depends on \( R_1 \) if there is a piece-unifier of \( B_2 \) with \( H_1 \), satisfying some easily checked additional conditions (atom erasing \( \epsilon \) and usefulness \( \epsilon \)). Following Example 4 illustrates the difference between piece-unification and classical unification.

Example 4 (Rule dependency) Let \( R_1 \) and \( R_2 \) from Example 2. Although the atoms \( p(u, v) \in B_2 \) and \( p(x, y) \in H_1 \) are unifiable, there is no piece-unifier of \( B_2 \) with \( H_1 \). Indeed, the most general unifier \( \mu = \{ (u, x), (v, y) \} \) (or, equivalently, \{ (u, x), (y, v) \}), with \( B_2' = \{ p(u, v) \} \) and \( H_1' = H_1 \), is not a piece-unifier because \( v \) is unified with an existential variable, whereas it is a separating variable of \( B_2' \) (thus, \( q(v) \) should be included in \( B_2' \)). It follows that \( R_2 \) does not depend on \( R_1 \).

The graph of rule dependencies of a set of rules \( \mathcal{R} \), denoted by \( \text{GRD}(\mathcal{R}) \), is a directed graph with set of nodes \( \mathcal{R} \) and an edge \((R_i, R_j)\) if \( R_j \) depends on \( R_i \), e.g., with the rules in Example 4 the only edge is \((R_2, R_1)\). When the GRD is acyclic (\( a\text{GRD} \)), any derivation sequence is finite.

3.3 Combining both approaches

Both approaches are incomparable: there may be a dangerous cycle on positions but no cycle w.r.t. rule dependencies (Example 2 and 3).
and there may be a cycle w.r.t. rule dependencies whereas rules have no existential variables (e.g., \( p(x, y) \rightarrow p(y, x) \)). So far, attempts to combine both notions only succeeded to combine them in a “modular way”, by considering the strongly connected components (s.c.c.) of the GRD \([2,14]\); briefly, if a chase variant stops on each subset of rules associated with a s.c.c., then it stops on the whole set of rules. In this paper, we propose an “integrated” way of combining both approaches, which relies on a single graph. This allows to unify preceding results and to generalize them without increasing complexity. The new acyclicity notions are those with a gray background in Figure 1.

Finally, let us mention model-faithful acyclicity (mfa) \([12]\), which cannot be captured by our approach. Briefly, checking mfa involves running the skolem chase until termination or a cyclic functional term is found. The price to pay is high complexity: checking if a set of rules is model-faithful acyclic for any set of facts is \( 2 \text{EXPTIME} \)-complete. Checking model-summarizing acyclicity (msa) \([12]\), which approximates mfa, remains \( \text{EXPTIME} \)-complete. In contrast, checking position-based properties is in PTIME and checking aGRD is co-NP-complete.

Exp \[msa\]

2-Exp \[mfa\] ![Exp](msa) ![msaD](wa) ![waU](waU+)

Figure 1. Relations between recognizable acyclicity properties. All inclusions are strict and complete (i.e., if there is no path between two properties then they are incomparable).

It remains to specify for which chase variants the above acyclicity notions ensure termination. Since mfa generalizes all properties in Figure 1 and sets of rules satisfying mfa are skolem-finite, all these properties ensure \( C \)-finiteness, for any chase variant \( C \) at least as strong as the skolem chase. We point out that the oblivious chase may not stop on wa rules. Actually, the only acyclicity notion in Figure 1 that ensures the termination of the oblivious chase is aGRD, since all other notions generalize wa.

4 EXTENDING ACYCLICITY NOTIONS

In this section, we combine rule dependency and propagation of existential variables into a single graph. W.l.o.g. we assume that distinct rules do not share any variable. Given an atom \( a = p(t_1, \ldots, t_k) \), the \( i^{th} \) position in \( a \) is denoted by \([a,i]\), with \( \text{pred}([a,i]) = p \) and \( \text{term}([a,i]) = t_i \). If \( A \) is an atomset such that \([a,i] \in A \), we say that \([a,i] \in A \). If \( \text{term}([a,i]) \) is an existential (resp. frontier) variable, \([a,i] \) is called an existential (resp. frontier) position. In the following, we use “position graph” as a generic name to denote a graph whose nodes are positions in atoms.

We first define the notion of a basic position graph, which takes each rule in isolation. Then, by adding edges to this graph, we define three position graphs with increasing expressivity, i.e., allowing to check termination for increasingly larger classes of rules.

**Definition 1 ((Basic) Position Graph \((PG)\))** The position graph of a rule \( R : B \rightarrow H \) is the directed graph \( PG(R) \) defined as follows:

- there is a node for each \([a,i] \in B \) or \([h,j] \in H \);
- for all frontier positions \([b,i] \in B \) and all \([h,j] \in H \), there is an edge from \([b,i] \) to \([h,j] \) if \( \text{term}([b,i]) = \text{term}([h,j]) \) or if \([h,j] \) is existential.

Given a set of rules \( R \), the basic position graph of \( R \), denoted by \( PG(R) \), is the disjoint union of \( PG(R_i) \), for all \( R_i \in R \).

An existential position \([a,i] \) is said to be infinite if there is an atomset \( F \) such that running the chase on \( F \) produces an unbounded number of instantiations of \( \text{term}([a,i]) \). To detect infinite positions, we encode how variables may be “propagated” among rules by adding edges to \( PG(R) \), called transition edges, which go from positions in rule heads to positions in rule bodies. The set of transition edges has to be correct: if an existential position \([a,i] \) is infinite, there must be a cycle going through \([a,i] \) in the graph.

We now define three position graphs by adding transition edges to \( PG(R) \), namely \( PG^F(R) \), \( PG^D(R) \) and \( PG^U(R) \). All three graphs have correct sets of edges. Intuitively, \( PG^F(R) \) corresponds to the case where all rules are supposed to depend on all rules; its set of cycles is in bijection with the set of cycles in the predicate position graph defining weak-acyclicity. \( PG^D(R) \) encodes actual paths of rule dependencies. Finally, \( PG^U(R) \) adds information about the piece-unifiers themselves. This provides an accurate encoding of variable propagation from an atom position to another.

**Definition 2 \((PG^X)\)** Let \( R \) be a set of rules. The three following position graphs are obtained from \( PG(R) \) by adding a (transition) edge from each \( k^{th} \) position \([h,k] \) in a rule head \( H_k \) to each \( k^{th} \) position \([b,k] \) in a rule body \( B_j \), with the same predicate, provided that some condition is satisfied:

- full PG, denoted by \( PG^F(R) \); no additional condition;
- dependency PG, denoted by \( PG^D(R) \); if \( R_j \) depends directly or indirectly on \( R_i \), i.e., if there is a path from \( R_i \) to \( R_j \) in GRD(R);
- PG with unifiers, denoted by \( PG^U(R) \); if there is a piece-unifier \( \mu \) of \( B_j \) with the head of the agglomerated rule \( R'_i \) such that \( \mu(\text{term}([b,k])) = \mu(\text{term}([h,k])) \), where \( R'_i \) is formally defined below (Definition 3).

An agglomerated rule associated with \((R_i, R_j)\) gathers information about selected piece-unifiers along (some) paths from \( R_i \) to (some) predecessors of \( R_j \).
There is a piece-unifier $l < n$ by building a sequence $P G$. Figure 2.

Definition 3 (Agglomerated Rule) Let $R_i$ be an agglomerated rule associated with $(R_1, R_2)$. The agglomerated rule $R_i$ built from $\{R_i|P \in P\}$ is $R_i = B_i \cup_{i \in T \subseteq \text{terms}(R)} f_t(t) \rightarrow H_i$.

The following inclusions follow from the definitions:

Proposition 1 (Inclusions between $PG^X$) Let $R$ be a set of rules. $PG^X(\mathcal{R}) \subseteq PG^D(\mathcal{R}) \subseteq PG^F(\mathcal{R})$. Furthermore, $PG^D(\mathcal{R}) = PG^F(\mathcal{R})$ if the transitive closure of GRD$(\mathcal{R})$ is a complete graph.

Example 4 ($PG^F$ and $PG^D$) Let $\mathcal{R} = \{R_1, R_2\}$ from Example 2. Figure 2 pictures $PG^F(\mathcal{R})$ and $PG^D(\mathcal{R})$. The dashed edges belong to $PG^D(\mathcal{R})$ but not to $PG^F(\mathcal{R})$. Indeed, $P_2$ does not depend on $R_1$, $PG^D(\mathcal{R})$ has a cycle while $PG^F(\mathcal{R})$ has not.

Example 5 ($PG^D$ and $PG^U$) Let $\mathcal{R} = \{R_1, R_2\}$, with $R_1 \equiv (x, y) \rightarrow p(x, y), (y, y)$ and $R_2 \equiv p(u, v), q(u) \rightarrow (v, w)$. In Figure 3 the dashed edges belong to $PG^U(\mathcal{R})$ but not to $PG^D(\mathcal{R})$. Indeed, the only piece-unifier of $B_2$ with $H_1$ unifies $u$ and $y$. Hence, the cycle in $PG^D(\mathcal{R})$ disappears in $PG^U(\mathcal{R})$.

We now study how acyclicity properties can be expressed on position graphs. The idea is to associate, with an acyclicity property, a function that assigns to each position a subset of positions reachable from this position, according to some propagation constraints; then, the property is fulfilled if no existential position can be reached from itself. More precisely, a marking function $Y$ assigns to each node $[a, i]$ in a position graph $PG^X$, a subset of its (direct or indirect) successors, called its marking. A marked cycle for $[a, i]$ (w.r.t. $X$ and $Y$) is a cycle $C$ in $PG^X$ such that $[a, i] \in C$ and for all $[a', i'] \in C$, $[a', i']$ belongs to the marking of $[a, i]$. Obviously, the less situations there are in which the marking may “propagate” in a position graph, the stronger the acyclicity property is.

Definition 4 (Acyclicity property) Let $Y$ be a marking function and $PG^X$ be a position graph. The acyclicity property associated with $Y$ in $PG^X$, denoted by $Y^X$, is satisfied if there is no marked cycle for an existential position in $PG^X$. If $Y^X$ is satisfied, we also say that $PG^X(\mathcal{R})$ satisfies $Y$.

For instance, the marking function associated with weak-acyclicity assigns to each node the set of its successors in $PG^F(\mathcal{R})$, without any additional constraint. The next proposition states that such marking functions can be defined for each class of rules between $wa$ and $swa$ (first column in Figure 1), in such a way that the associated acyclicity property in $PG^F$ characterizes this class.

Proposition 2 A set of rules $\mathcal{R}$ is $wa$ (resp. $fd$, ar, ja, swa) iff $PG^F(\mathcal{R})$ satisfies the acyclicity property associated with wa- (resp. $fd$, ar-, ja-, swa-) marking.

As already mentioned, all these classes can be safely extended by combining them with the GRD. To formalize this, we recall the notion $Y^C$ of an acyclicity property $Y$, a set of rules $\mathcal{R}$ is said to satisfy $Y^C$ if each s.c.c. of $GRD(\mathcal{R})$ satisfies $Y$, except for those composed of a single rule with no loop. Whether $\mathcal{R}$ satisfies $Y^C$ can be checked on $PG^D(\mathcal{R})$.

Proposition 3 Let $\mathcal{R}$ be a set of rules, and $Y$ be an acyclicity property. $\mathcal{R}$ satisfies $Y^C$ iff $PG^D(\mathcal{R})$ satisfies $Y$, i.e., $Y^C = Y^D$.

For the sake of brevity, if $Y_1$ and $Y_2$ are two acyclicity properties, we write $Y_1 \subseteq Y_2$ if any set of rules satisfying $Y_1$ also satisfies $Y_2$. The following results are straightforward.

Proposition 4 Let $Y_1, Y_2$ be two acyclicity properties. If $Y_1 \subseteq Y_2$, then $Y_1^D \subseteq Y_2^D$.

Proposition 5 Let $Y$ be an acyclicity property. If $aGRD \not\subseteq Y$ then $Y \not\subset Y^D$.

Hence, any class of rules satisfying a property $Y^D$ strictly includes both $aGRD$ and the class characterized by $Y$; (e.g., Figure 1 from Column 1 to Column 2). More generally, strict inclusion in the first column leads to strict inclusion in the second one:

Proposition 6 Let $Y_1, Y_2$ be two acyclicity properties such that $Y_1 \subset Y_2$. $wa \subseteq Y_1$ and $Y_2 \not\subseteq Y_1^D$. Then $Y_1^D \subset Y_2^D$.

The next theorem states that $PG^U$ is strictly more powerful than $PG^D$; moreover, the “jump” from $Y^D$ to $Y^U$ is at least as large as from $Y$ to $Y^D$.

\footnote{This particular case is to cover aGRD, in which each s.c.c. is an isolated node.}
Theorem 1 Let Y be an acyclicity property. If Y ⊂ Y^D then Y^D ⊂ Y^U. Furthermore, there is an injective mapping from the sets of rules satisfying Y^D but not Y, to the sets of rules satisfying Y^U but not Y^D.

Proof: Assume Y ⊂ Y^D and R satisfies Y^D but not Y. R can be rewritten into Y by applying the following steps. First, for each rule R_i = B_i \rightarrow H_i, let R_{i,1} = B_i \rightarrow p_i(\vec{x},\vec{y}) where p_i is a fresh predicate; and R_{i,2} = p_i(\vec{x},\vec{y}) \rightarrow H_i for each cycle in Y. Then, for each rule R_{i,1}, let R'_{i,1} be the rule (B_{i,1} \rightarrow H_{i,1}) with B_{i,1} = B_i \cup \{p_j'(r_i(z_j)) : \forall R_j \in R\}, where p_j' are fresh predicates and x_j, y_j new fresh variables. Now, for each cycle R_{i,2}, let R'_{i,2} be the rule (B_{i,2} \rightarrow H_{i,2}) with H_{i,2} = H_{i,2} \cup \{p_j'(z_j) : \forall R_j \in R\}, where z_j is a fresh existential variable. Let R' = \bigcup_{R_i \in R} \{R'_{i,1}, R'_{i,2}\}. This construction ensures that each R'_{i,2} depends on R'_{i,1}, and each R'_{i,1} depends on each R'_{i,2}, thus, there is a transition edge from each R'_{i,1} to R'_{i,2} and from each R'_{i,2} to each R'_{i,1}. Hence, P^G(D(R')) contains exactly one cycle for each cycle in P^G(D(R)). Furthermore, P^G(U(R')) contains at least one marked cycle w.r.t. Y, and then R' does not satisfy Y^U. Now, each cycle in P^G(U(R')) is also a cycle in P^G(U(R)), and, since P^G(U(R)) satisfies Y, P^G(U(R')) also does. Hence, R' does not belong to Y^U but to Y^U. \qed

We also check that strict inclusions in the second column in Figure 3 lead to strict inclusions in the third column.

Theorem 2 Let Y_1 and Y_2 be two acyclicity properties. If Y^D \subset Y^U then Y^U \subset Y^D.

Proof: Let R be a set of rules such that R satisfies Y^D but does not satisfy Y^U. We rewrite R into R' by applying the following steps. For each pair of rules R_i, R_j in R such that there is a dependency path from R_i to R_j, for each variable x in the frontier of R_j and each variable y in the head of R_i, if x and y occur both in a given predicate position, we add to the body of R_i a new atom p_{i,j,x,y}(x) and to the head of R_j a new atom p_{i,j,x,y}(y) where p_{i,j,x,y} denotes a fresh predicate. This construction allows each term from the head of R_i to propagate to each term from the body of R_j, if they share some predicate position in R. Thus, any cycle in P^G(U(R)) is also in P^G(U(R')), without any change in the behavior w.r.t. the acyclicity properties. Hence R' satisfies Y^U but does not satisfy Y^U. \qed

The next result states that Y^U is a sufficient condition for chase termination:

Theorem 3 Let Y be an acyclicity property ensuring the halting of some chase variant C. Then, the C-chase halts for any set of rules R that satisfies Y^U (hence Y^D).

Example 6 Consider again the set of rules R from Example 3. Figure 3 pictures the associated position graph P^G(D(R)) and P^G(U(R)). R is not aGRD, nor wa, nor waD since P^G(D(R)) contains a (marked) cycle that goes through the existential position [t(v, w), 2]. However, R is obviously waD since P^G(U(R)) is acyclic. Hence, the skolem chase and stronger chase variants halt for R and any set of facts.

Finally, we remind that classes from wa to swa can be recognized in PTIME, and checking aGRD is co-NP-complete. Hence, as stated by the next result, the expressiveness gain is without increasing worst-case complexity.

Theorem 4 (Complexity) Let Y be an acyclicity property, and R be a set of rules. If checking that R satisfies Y is in co-NP, then checking that R satisfies Y^D or Y^U is co-NP-complete.

5 FURTHER REFINEMENTS

In this section, we show how to further extend Y^U into Y^U^+ by a finer analysis of marked cycles and unifiers. This extension can be performed without increasing complexity. We define the notion of incompatible sequence of unifiers, which ensures that a given sequence of rule applications is impossible. Briefly, a marked cycle for which all sequences of unifiers are incompatible can be ignored. Beside the gain for positive rules, this refinement will allow one to take better advantage of negation.

We first point out that the notion of piece-unifier is not appropriate to our purpose. We have to relax it, as illustrated by the next example.

We call unifier, of a rule body B_2 with a rule head H_1, a substitution \mu of vars(B_2) \cup vars(H_1), where B_2 \subset B_1 and H_1 \subset H_1, such that \mu(B_2) = \mu(H_1) (thus, it satisfies Condition (1) of a piece-unifier).

Example 7 Let R = \{R_1, R_2, R_3, R_4\} with:

R_1: p(x_1, y_1) \rightarrow s(y_1, z_1)
R_2: q(x_2, y_2) \rightarrow r(x_2, y_2)
R_3: r(x_3, y_3) \land s(x_3, y_3) \rightarrow p(x_3, y_3)
R_4: q(x_4, y_4) \rightarrow s(x_4, y_4)

There is a dependency cycle (R_1, R_2, R_3, R_4) and a corresponding cycle in P^G(U). We want to know if such a sequence of rule applications is possible. We build the following new rule, which is a composition of R_1 and R_2 (formally defined later): R_1 \circ_o R_2: p(x_1, y_1) \rightarrow q(y_1, z_1) \land r(y_1, z_1)

There is no piece-unifier of R_2 with R_1 \circ_o R_2, since \mu_3 would be a separating variable mapped to the existential variable z_1. This actually means that R_3 is not applicable right after R_1 \circ_o R_2. However, the atom needed to apply s(x_3, y_3) can be brought by a sequence of rule applications (R_1, R_3). We thus relax the notion of piece-unifier to take into account arbitrarily long sequences of rule applications.

Definition 5 (Compatible unifier) Let R_1 and R_2 be rules. A unifier \mu of B_2 with H_1 is compatible if, for each position [a, i] in B_2, such that \mu(term([a, i])) is an existential variable z in H_1, P^G(U(R)) contains a path, from a position in which z occurs, to [a, i], that does not go through another existential position. Otherwise, \mu is incompatible.

Note that a piece-unifier is necessarily compatible.

Proposition 7 Let R_1 and R_2 be rules, and let \mu be a unifier of B_2 with H_1. If \mu is compatible, then no application of R_2 can use an atom in \mu(H_1).

We define the rule corresponding to the composition of R_1 and R_2 according to a compatible unifier, then use this notion to define a compatible sequence of unifiers.

Definition 6 (Unified rule, Compatible sequence of unifiers)

Let R_1 and R_2 be rules such that there is a compatible unifier \mu of B_2 with H_1. The associated unified rule R_\mu = R_1 \circ_o R_2 is defined by H_\mu = \mu(H_1) \cup \mu(H_2), and B_\mu = \mu(B_1) \cup \{\mu(B_2) \setminus \mu(H_1)\}.

Let (R_1, \ldots , R_\ell) be a sequence of rules. A sequence s = (R_1, \mu_1, R_2, \ldots , \mu_k, R_{k+1}), for which 1 \leq t \leq k, \mu_t is a unifier of B_{t+1} with H_t is a compatible sequence of unifiers if: (1) \mu_1 is a compatible unifier of B_2 with H_1, and (2) if k > 0, the sequence obtained from s by replacing (R_1, \mu_1, R_2) with R_1 \circ_o R_2 is a compatible sequence of unifiers.

E.g., in Example 7 the sequence (R_1, \mu_1, R_2, R_3, \mu_3, R_4), with the obvious \mu_3, is compatible. We can now improve all previous acyclicity properties (see the fourth column in Figure 3).
and of rule dependency: to define $\mu$ solvers that instantiate rules on the fly \cite{21,13}.

We can also extend them by exploiting negation. We consider a cycle of positive reliance involves a rule with an existential variable. Indeed, our acyclicity criteria essentially ensure that there is a finite normal logic programs). We can rely on the standard definition of stable models \cite{16}, and that satisfies $Y^{U^+}$ (hence $Y^U$). Finally, the complexity result from Theorem 4 still holds for this improvement.

\section{Extension to Nonmonotonic Negation}

We now add nonmonotonic negation, which we denote by $\text{not}$. A nonmonotonic existential (NME) rule $R$ is of the form $\forall y \in \mathcal{Y}(B^+ \land \text{not} B_1^- \land \ldots \land \text{not} B_m^- \rightarrow \exists \mathcal{H})$, where $B^+$, $B^-$ is a set of atoms, respectively called the positive body, the negative body and the head of $R$; furthermore, $\text{vars}(B^-) \subseteq \text{vars}(B^+)$. $R$ is applicable to $F$ if there is a homomorphism $h$ from $B^+$ to $F$ such that $h(B^-) \cap F = \emptyset$. In this section, we rely on a skolemization of the knowledge base. Then, the application of $R$ to $F$ w.r.t. $h$ produces $h(\text{sk}(H))$. $R$ is self-blocking if $B^- \cap (B^+ \cup H) \neq \emptyset$, i.e., $R$ is never applicable.

Since skolemized NME rules can be seen as normal logic programs, we can rely on the standard definition of stable models \cite{16}, which we omit here since it is not needed to understand the sequel. Indeed, our acyclicity criteria essentially ensure that there is a finite number of skolemized rule applications. Although the usual definition of stable models relies on grounding (i.e., instantiating) skolemized rules, stable models of $(\mathcal{F},\mathcal{R})$ can be computed by a skolem chase-like procedure, as performed by Answer Set Programming solvers that instantiate rules on the fly \cite{21,13}.

We check that, when the skolem chase halts on the positive part of NME rules (i.e., obtained by ignoring the negative body), the stable computation based on the skolem chase halts. We can thus rely on preceding acyclicity conditions, which already generalize known acyclicity conditions applicable to skolemized NME rules (for instance finite-domain and argument-restricted skolemization, which were defined for normal logic programs). We can also extend them by exploiting negation.

First, we consider the natural extensions of a unified rule (Def. 9) and of rule dependency: to define $R_0 = R_1 \circ_R R_2$, we add that $B_0^- = \mu(B_1^+) \cup \mu(B_2^+)$; besides, $R_2$ depends on $R_1$ if there is a piece-unifier $\mu$ of $H_2$ with $B_1$ such that $R_1 \circ_R R_2$ is not self-blocking; if $R_1 \circ_R R_2$ is self-blocking, we say that $\mu$ is self-blocking. Note that this extended dependency is equivalent to the positive reliance from \cite{29}. In this latter paper, positive reliance is used to define an acyclicity condition: a set of NME rules is said to be $R$-acyclic if no cycle of positive reliance involves a rule with an existential variable. Consider now $PGD^D$ with extended dependency: then, $R$-acyclicity is stronger than aGRD (since cycles are allowed on rules without existential variables) but weaker than waD (since all s.c.c. are necessarily wa).

By considering extended dependency, we can extend the results obtained with $PGD^D$ and $PGD^+$ (note that for $PGD^+$ we only encode non-self-blocking unifiers). We can further extend $Y^{U^+}$ classes by considering self-blocking compatible sequences of unifiers. Let $C$ be a compatible cycle for $[a, i]$ in $PGD^D$, and $C_\mu$ be the set of all compatible sequences of unifiers induced by $C$. A sequence $\mu_1, \ldots, \mu_k \in C_\mu$ is said to be self-blocking if the rule $R_1 \circ_R \ldots \circ_R R_k \in \mu_1$ is self-blocking. When all sequences in $C_\mu$ are self-blocking, $C$ is said to be self-blocking.

Example 8 Let $R_1 = q(x_1), \text{not} p(x_1) \rightarrow r(x_1, y_1), R_2 = r(x_2, y_2) \rightarrow s(x_2, y_2), R_3 = s(x_3, y_3) \rightarrow p(x_3), q(y_3), PGD^+\{(R_1, R_2, R_3)\}$ has a unique cycle, with a unique induced compatible unifier sequence. The rule $R_1 \circ_R R_2 \circ_R R_3 = q(x_1), \text{not} p(x_1) \rightarrow r(x_1, y_1), s(x_1, y_1), p(x_1), q(y_1)$ is self-blocking, hence $R_1 \circ_R R_2 \circ_R R_3$ also is. Thus, there is no dangerous cycle.

Proposition 8 If, for each existential position $[a, i]$, all compatible cycles for $[a, i]$ in $PGD^+$ are self-blocking, then the stable computation based on the skolem chase halts.

Finally, we point out that these improvements do not increase worst-case complexity of the acyclicity test.

\section{Conclusion}

We have proposed a tool that allows to unify and generalize most existing acyclicity conditions for existential rules, without increasing worst-case complexity. This tool can be further refined to deal with nonmonotonic (skolemized) existential rules, which, to the best of our knowledge, extends all known acyclicity conditions for this kind of rules.

Further work includes the implementation of the tool\cite{21} and experiments on real-world ontologies, as well as the study of chase variants that would allow to process existential rules with stable negation without skolemization.

### Appendix

#### Proposition 2

* A set of rules $\Gamma$ is wa (resp. fd, ar, ja, swa) iff $\Gamma^w(R)$ satisfies the acyclicity property associated with the wa-marking (resp. fd, ar, ja, swa-marking).

To prove Proposition 2, we rely on some intermediary results. The next proposition is immediate.

#### Proposition 9

* For each edge $(p, q)$ in the predicate position graph of a set of rules $\Gamma$, there is the following non-empty set of edges in $\Gamma^w(R)$: $E_{p, q} = \{(a, i), (a', j)\} \mid \text{pred}(a, i) = p \text{ and pred}(a', j) = q\}$.

Furthermore, these sets of edges form a partition of all edges in $\Gamma^w(R)$.

We now define marking functions, whose associated acyclicity property corresponds to wa, fd, ar, ja or swa when it is applied on $\Gamma^w(R)$. The following three conditions, defined for a marking $M[(a, i)]$, make it easy to compare known acyclicity properties.

- **(P1)** $\Gamma^w([a, i]) \subseteq M([a, i])^{\Gamma\c}$
- **(P2)** for all $[a', i'] \in M([a, i])$ such that $[a', i']$ occurs in some rule head: $\Gamma^+([a', i']) \subseteq M([a, i])$
- **(P3)** for all variable $v$ in a rule body, such that for all position $[a', i']$ with $\text{term}([a', i']) = v$, there is $[a', i'] \in M([a, i])$ with $\text{pred}([a', i']) = \text{pred}([a', i'])$ and $\text{term}([a', i']) = v$: $\Gamma^+(v) \subseteq M([a, i])$, where $\Gamma^+(v)$ is the union of all $\Gamma^+(p)$, where $p$ is an atom position in which $v$ occurs.

**(P1)** ensures that the marking of a given node includes its successors; **(P2)** ensures that the marking includes the successors of all marked nodes from a rule head; and **(P3)** ensures that for each frontier variable of a rule such that all predicate positions where it occurs are marked, the marking includes its successors.

#### Definition 8 (Weak-acyclicity marking)

A marking $M$ is a wa-marking w.r.t $X$ if for any $[a, i] \in PGX$, $M([a, i])$ is the minimal set such that:

- **(P1)** holds,
- for all $[a', i'] \in M([a, i])$, $\Gamma^+([a', i']) \subseteq M([a, i])$

**Observation:** The latter condition implies (P2) and (P3).

#### Proposition 10

* A set of rules $\Gamma$ is wa iff $\Gamma^w(R)$ satisfies the acyclicity property associated with the wa-marking.

Proof: If $\Gamma$ is not wa, then there is some cycle in the graph of predicate positions going through a special edge. Let $p_i$ be the predicate position where this edge ends, and $z$ be the existential variable which occurs in $p_i$. Let $M$ be the wa-marking of any existential position $[a, i]$ with $\text{pred}([a, i]) = p$ and $\text{term}([a, i]) = z$.

**(P1)** ensures that the successors of $[a, i]$ are marked; then, the propagation function will perform a classic breadth-first traversal of the graph. By Proposition 9 to each cycle in the graph of predicate positions of $R$ corresponds a set of cycles in $\Gamma^w(R)$. Since $p_i$ belongs to a cycle, $[a, i]$ will obviously be marked by the propagation function. Hence, $\Gamma^w(R)$ does not satisfy the associated acyclicity property of the wa-marking.

Conversely, if $\Gamma$ is wa, there is no cycle going through a special edge in the graph of predicate positions of $R$. By Proposition 9 to any node $v$, $\Gamma^+(v)$ denotes the set of (direct) successors of $v$. 

---

<sup>[5]</sup> For any node $v$, $\Gamma^+(v)$ denotes the set of (direct) successors of $v$. <sup>[6]</sup>
each cycle in $PG^F(\mathcal{R})$ corresponds a cycle in the graph of predicate positions of $\mathcal{R}$, hence no cycle in $PG^F(\mathcal{R})$ goes through an existential position.

We do not recall here the original definitions of $fd$, $ar$, $ja$, $swa$. The reader is referred to the papers cited in Section 4 or to [12], where these notions are reformulated with a common vocabulary.

**Definition 9 (Finite domain marking)** A marking $M$ is a $fd$-marking wrt $X$ if for any $[a,i] \in PG^X$, $M([a,i])$ is the minimal set such that:
- (P1) and (P3) hold,
- for all $[a',i'] \in M([a,i]), \Gamma^+([a',i']) \setminus \{[a,i]\} \subseteq M([a,i])$.

Observation: The latter condition implies (P2).

**Proposition 11** A set of rules $\mathcal{R}$ is $fd$ iff $PG^F(\mathcal{R})$ satisfies the acyclicity property associated with the $fd$-marking.

**Proof:** Let $\mathcal{R}$ be a set of rules that is $fd$, then for each existential position $p_i$ there exists a position $p_j$ for each variable of the frontier in the graph of predicate positions such that $p_j$ does not belong to a cycle. Given $PG^F(\mathcal{R})$ we can see that Condition (P3) ensures that $\mathcal{R}$ is $fd$.

**Definition 10 (Argument restricted marking)** A marking $M$ is an $ar$-marking wrt $X$ if for any $[a,i] \in PG^X$, $M([a,i])$ is the minimal set such that:
- (P1), (P2) and (P3) hold,
- for each existential position $[a',i']$, $\Gamma^+([a',i']) \subseteq M([a,i])$.

Observation: If $M$ is an $ar$-marking, then for all existential positions $[a,i],[a',i'] \in PG^X$, $M([a,i]) = M([a',i'])$.

**Proposition 12** A set of rules $\mathcal{R}$ is $ar$ iff $PG^F(\mathcal{R})$ satisfies the acyclicity property associated with the $ar$-marking.

**Proof:** Let $\mathcal{R}$ be a set of rules that is $ar$, then there exists a ranking on terms (i.e., arguments) such that for each rule the rank of an existential variable needs to be strictly higher than the rank of each frontier variable in the body and the rank of a frontier variable in the head has to be higher or equal to the rank of this frontier variable in the body. The ranking process is equivalent to the ranking, in fact each time a node is marked, the rank of a term is incremented. If we have a cyclic $ar$-marking, it means that there exists at least one term rank that does not satisfy the property of argument-restricted. We can see the ranking process as a method to compute an argument ranking.

**Definition 11 (Joint acyclicity marking)** A marking $M$ is a $ja$-marking wrt $X$ if for any $[a,i] \in PG^X$, $M([a,i])$ is the minimal set such that (P1), (P2) and (P3) hold.

**Proposition 13** A set of rules $\mathcal{R}$ is $ja$ iff $PG^F(\mathcal{R})$ satisfies the acyclicity property associated with the $ja$-marking.

**Proof:** The definition of the $ja$ propagation function is the same as in [13]. Indeed the “Move” set of a position is defined in the same way as the marking. Furthermore, by Proposition 3 for any predicate position $p_i$ in the graph of joint-acyclicity, there is a cycle going through $p_i$ iff for any existential atom position $[a,i]$ such that $\text{pred}([a,i]) = p$, we have $[a,i] \in M([a,i])$.

**Definition 12 (Super-weak-acyclicity marking)** A marking $M$ is a $swa$-marking wrt $X$ if for any $[a,i] \in PG^X$, $M([a,i])$ is the minimal set such that:
- (P1) and (P3) hold,
- for all $[a',i'] \in M([a,i])$ occurring in a rule head, $\{a'',i''\} \in \Gamma^+([a',i'])$: $a'$ and $a''$ unify $\subseteq M([a,i])$.

**Proposition 14** A set of rules $\mathcal{R}$ is $swa$ iff $PG^F(\mathcal{R})$ satisfies the acyclicity property associated with the $swa$-marking.

**Proof:** In the original paper of [23], the definition of $swa$ was slightly different from this marking, but it has been shown in [12], that $swa$ can be equivalently expressed by a “Move” set similar to $ja$. As for the $ja$-marking, the definition of the $swa$-marking corresponds to the definition of its “Move” set.

**Proof of Proposition 3** Follows from Propositions 10[11][12][13] and[14].

**Proposition 6** Let $Y_1$ and $Y_2$ be two acyclicity properties such that $Y_1 \subseteq Y_2$, $wa \subseteq Y_1$ and $Y_2 \not\subseteq Y_1$. Then $Y_1^{BD} \subseteq Y_2^{BD}$.

**Proof:** Let $\mathcal{R}$ be a set of rules such that $\mathcal{R}$ satisfies $Y_1$ and not $Y_2$, nor $\text{GRD}(\mathcal{R})$. $\mathcal{R}$ can be rewritten into $\mathcal{R}'$ by replacing each rule $R_i = (B_i, H_i) \in \mathcal{R}$ with a new rule $R_i' = (B_i \cup \{p(x)\}, H_i \cup \{p(x)\})$ where $p$ is a fresh predicate and $x$ a fresh variable. Each rule can now be unified with each rule, but the only created cycles are those which contain only atoms $p(x)$, hence none of those cycles go through existential positions. Since $wa \subseteq Y_1$ (and so $wa \subseteq Y_2'$), the added cycles do not change the behavior of $\mathcal{R}$ w.r.t. $Y_1$ and $Y_2$. Hence, $\mathcal{R}'$ is a set of rules satisfying $Y_1$ and not $Y_2$, and since $\text{GRD}(\mathcal{R}')$ is a complete graph, $PG^D(\mathcal{R}') = PG^D(\mathcal{R})$. We can conclude that $Y_2'$ satisfies $Y_2$ but not $Y_1$.

**Theorem 1** Let $Y$ be an acyclicity property. If $Y \subseteq Y^D$ then $Y^D \subseteq Y^U$. Furthermore, there is an injective mapping from the sets of rules satisfying $Y^D$ but not $Y$, to the sets of rules satisfying $Y^U$ but not $Y^D$.

**Proof:** (included in the paper) Assume $Y \subseteq Y^D$ and $\mathcal{R}$ satisfies $Y^D$ but not $Y$. $\mathcal{R}$ can be rewritten into $\mathcal{R}'$ by applying the following steps. First, for each rule $R_i = B_i[x, \bar{y}] \rightarrow H_i[y, \bar{z}] \in \mathcal{R}$, let $R_{i,1} = B_i[x, \bar{y}] \rightarrow p_i(\bar{x}, \bar{y})$ where $p_i$ is a fresh predicate and $R_{i,2} = p_i(\bar{x}, \bar{y}) \rightarrow H_i[y, \bar{z}]$. Then, for each rule $R_{i,1}$, let $R_{i,1}'$ be the rule $(B_{i,1}' \rightarrow H_{i,1})$ with $B_{i,1}' = B_i, \bigcup \{p_{i,j}(x_{i,j}) : \forall R_j \in R\}$, where $p_{i,j}$ are fresh predicates and $x_{i,j}$ fresh variables. Now, for each rule $R_{i,2}$ let $R_{i,2}'$ be the rule $(B_{i,2}' \rightarrow H_{i,2})$ with $H_{i,2}' = H_{i,2}, \bigcup \{p_{i,j}(x_{i,j}) : \forall R_j \in R\}$, where $x_{i,j}$ are fresh existential variables. Let $\mathcal{R}' = \bigcup_{R_i \in \mathcal{R}} R'_{i,1}, R'_{i,2}$. This construction ensures that each $R'_{i,2}$ depends on $R'_{i,1}$, and each $R'_{i,1}$ depends on each $R'_{i,2}$. Thus, there is a transition edge from each $R'_{i,1}$ to $R'_{i,2}$ and from each $R'_{i,2}$ to each $R'_{i,1}$. Hence, $PG^D(\mathcal{R}')$ contains exactly one cycle for each cycle in $PG^F(\mathcal{R})$. Furthermore, $PG^D(\mathcal{R}')$ contains at least one marked cycle w.r.t. $Y$, and then $\mathcal{R}'$ is not $Y^D$. Now, each cycle in $PG^F(\mathcal{R}')$ is also a cycle in $PG^D(\mathcal{R})$, and since $PG^D(\mathcal{R})$ satisfies $Y$, $PG^D(\mathcal{R})$ also does. Hence, $\mathcal{R}'$ does not belong to $Y^D$ but to $Y^U$.

**Theorem 2** Let $Y_1$ and $Y_2$ be two acyclicity properties. If $Y_1^{BD} \subseteq Y_2^{BD}$ then $Y_1^{UD} \subseteq Y_2^{UD}$.

**Proof:** (included in the paper) Let $\mathcal{R}$ be a set of rules such that $\mathcal{R}$ satisfies $Y_2^{BD}$ but does not satisfy $Y_1^{BD}$. We rewrite $\mathcal{R}$ into $\mathcal{R}'$ by
applying the following steps. For each pair of rules \(R_i, R_j \in \mathcal{R}\) such that \(R_j\) depends on \(R_i\), for each variable \(x\) in the frontier of \(R_j\) and each variable \(y\) in the head of \(R_i\), if \(x\) and \(y\) occur both in a given predicate position, we add to the body of \(R_j\) a new atom \(p_{i,j,x,y}(x)\) and to the head of \(R_i\), a new atom \(p_{i,j,x,y}(y)\), where \(p_{i,j,x,y}\) denotes a fresh predicate. This construction will allow each term from the head of \(R_j\) to propagate to each term from the body of \(R_j\), if they shared some predicate position in \(\mathcal{R}\). Thus, any cycle in \(PG^D(\mathcal{R})\) is also in \(PG^U(\mathcal{R})\), without modifying behavior w.r.t. the acyclicity properties. Hence, \(\mathcal{R}'\) satisfies \(Y^U\) but does not satisfy \(Y^D\). □

**Theorem 5** Let \(Y\) be an acyclicity property ensuring the halting of some chase variant \(C\). Then the C-chase halts for any set of rules \(\mathcal{R}\) that satisfies \(Y^U\) (hence \(Y^D\)).

We will first formalize the notion of a *correct* position graph (this notion being not precisely defined in the core paper). Then, we will prove that \(PG^D, PG^U\) and \(PG^D\) are correct, which will allow to prove the theorem.

**Preliminary definitions** Let \(F\) be a fact and \(\mathcal{R}\) be a set of rules. An \(\mathcal{R}\)-derivation (sequence) \((F_0 = F, (R_1, \pi_1, F_1), \ldots, (R_n, \pi_n, F_n))\) is a finite sequence \((F_0 = F, (R_1, \pi_1, F_1), \ldots, (R_n, \pi_n, F_n))\) such that for all \(0 < i \leq k\), \(R_i \in \mathcal{R}\) and \(\pi_i\) is a homomorphism from body \((R_i)\) to \(F_{i-1}\) such that \(F_i = \pi_i(F_{i-1}, \pi_i, R_i, \pi_i)\). When only the successive facts are needed, we note \((F_0 = F, F_1, \ldots, F_k)\).

Let \(S = (F_0 = F, \ldots, F_n)\) be a breadth-first \(\mathcal{R}\)-derivation from \(F\). Let \(h\) be an atom in the head of \(R_i\) and \(b\) be an atom in the body of \(R_j\). We say that \((h, \pi_i, b)\) is a support of \((b, \pi_j)\) (in \(S\)) if \(\pi_i^{\text{fast}}(h) = \pi_j(b)\). We also say that an atom \(f \in F_0\) is a support of \((b, \pi_j)\) if \(\pi_j(b) = f\). In that case, we note \((f, \text{init})\) is a support of \((b, \pi_j)\). Among all possible supports for \((b, \pi_j)\), its first supports are the \((h, \pi_i)\) such that \(i\) is minimal or \(\pi_i = \text{init}\). Note that \((b, \pi_j)\) can have two distinct first supports \((h, \pi_i)\) and \((h', \pi_i)\) when the body of \(R_i\) contains two distinct atoms \(h\) and \(h'\) such that \(\pi_i^{\text{fast}}(h) = \pi_i^{\text{fast}}(h')\). By extension, we say that \((R_i, \pi_i)\) is a support of \((R_j, \pi_j)\) in \(S\) when there exist an atom \(h\) in the head of \(R_i\) and an atom \(b\) in the body of \(R_j\) such that \((h, \pi_i)\) is a first support of \((b, \pi_j)\). In the same way, \(F_0\) is a support of \((R_i, \pi_i)\) when there exist \(b\) in the body of \(R_j\) such that \((b, \pi_j)\) \(\in F_0\). Among all possible supports for \((R_i, \pi_i)\), its last support is the support \((R_i, \pi_i)\) such that \(i\) is maximal.

The support graph of \(S\) has \(n + 1\) nodes, \(F_0\) and the \((R_i, \pi_i)\). We add an edge from \(I = (R_i, \pi_i)\) to \(J = (R_j, \pi_j)\) when \(J\) is a support of \(I\). Such an edge is called a last support edge (LS edge) when \(I\) is a last support of \(J\). An edge that is not LS is called non transitive (NT) if it is not a transitivity edge. A path in which all edges are either LS or NT is called a triggering path.

**Definition 13 (Triggering derivation sequence)** A \(h \rightarrow b\) triggering derivation sequence is a breadth-first derivation sequence \(F = F_0, \ldots, F_n\) from \(F\) where \((h, \pi_i)\) is a first support of \((b, \pi_n)\).

**Definition 14 (Correct position graph)** Let \(\mathcal{R}\) be a set of rules. A position graph of \(\mathcal{R}\) is said to be correct if, whenever there exists a \(h \rightarrow b\) triggering derivation sequence, the position graph contains a transition from \([h, i]\) to \([b, i]\) for all \(1 \leq i \leq k\), where \(k\) is the arity of the predicate of \(h\) and \(b\).

---

**Proposition 15** \(PG^D\) is correct.

**Proof:** Follows from the above definitions. □

**Lemma 1** If \(S\) is a \(h \rightarrow b\) triggering derivation sequence, then there is a triggering path from \((R_1, \pi_1)\) to \((R_n, \pi_n)\) in the support graph of \(S\).

**Proof:** There is an edge from \((R_1, \pi_1)\) to \((R_n, \pi_n)\) in the support graph of \(S\). By removing transitivity edges, it remains a path from \((R_1, \pi_1)\) to \((R_n, \pi_n)\) for which all edges are either LS or NT. □

**Lemma 2** If there is an edge from \((R_i, \pi_i)\) to \((R_j, \pi_j)\) that is either LS or NT in the support graph of \(S\), then \(R_i\) depends on \(R_j\).

**Proof:** Assume there is a LS edge from \((R_i, \pi_i)\) to \((R_j, \pi_j)\) in the support graph. Then the application of \(R_i\) according to \(\pi_i\), on \(F_{i-1}\) produces \(F_i\) on which all atoms required to map \(B_i\) are present (or it would not have been a last support). Since it is a support, there is also an atom required to map \(B_i\) that appeared in \(F_{i-1}\). It follows that \(R_i\) depends upon \(R_j\).

Suppose now that the edge is NT. Consider \(F_i\) such that there is a LS edge from \((R_k, \pi_k)\) to \((R_j, \pi_j)\). See that there is no path in the support graph from \((R_i, \pi_i)\) to \((R_k, \pi_k)\) (otherwise there would be a path from \((R_i, \pi_i)\) to \((R_j, \pi_j)\) and the edge would be a transitive edge). In the same way, there is no \(q\) such that there is a path from \((R_i, \pi_i)\) to \((R_j, \pi_j)\) that goes through \((R_k, \pi_k)\) (or the edge from \((R_i, \pi_i)\) to \((R_j, \pi_j)\) would be transitive). Thus, we can consider the atomset \(F_{\text{fr}}\) that would have been created by the following derivation sequence:

- first apply from \(F_0\) all rule applications of the initial sequence until \((R_{i-1}, \pi_{i-1})\);
- then apply all possible rule applications of this sequence, from \(i + 1\) until \(k\).

We can apply \((R_i, \pi_i)\) on the atomset \(F_{\text{fr}}\) thus obtained (since it contains the atoms of \(F_{i-1}\)). Let us now consider the atomset \(G\) obtained after this rule application. We must now check that \((R_j, \pi_j)\) can be applied on \(G\); this stems from the fact that there is no support path from \((R_i, \pi_i)\) to \((R_j, \pi_j)\). This last rule application relies upon an atom that is introduced by the application of \((R_i, \pi_i)\), thus \(R_j\) depends on \(R_i\). □

**Proposition 16** \(PG^U\) is correct.

**Proof:** If there is a \(h \rightarrow b\) triggering derivation sequence, then (by Lemma 1, we can exhibit a triggering path that corresponds to a path in the GRD (Lemma 2)). □

**Proposition 17** \(PG^U\) is correct.

**Proof:** Consider a \(h \rightarrow b\) triggering derivation sequence \(F = F_0, \ldots, F_n\). We note \(H^P = \pi_n(B_n) \cap \pi_0^{\text{fast}}(H_1)\) the atoms of \(F_n\) that are introduced by the rule application \((R_1, \pi_1)\) and are used for the rule application \((R_n, \pi_n)\). Note that this atomset \(H^P\) is not empty, since it contains at least the atom produced from \(h\). Now, consider the set of terms \(T^P = \text{terms}(H^P) \cap \text{terms}(\pi_n(B_n) \setminus H^P)\) that separate the atoms of \(H^P\) from the other atoms of \(\pi_n(B_n)\).

Now, we consider the rule \(R^P = B_1 \cup \{f(t) \mid t \text{ is a variable of } R_1\} \setminus \{f(t) \mid t \text{ is a term of } T^P\}\). #2
Consider the mapping \( \pi' \) from the variables of the body of \( R \) to those of \( F \), defined as follows: if \( v \) is a variable of \( B \), then \( \pi'(v) = \pi(v) \), otherwise \( v \) is a variable in an “fr” atom and \( \pi'(v) = \pi(v) \). This mapping is a homomorphism, thus we can consider the atomset \( F'' \) of \( F \), defined as follows: if \( v \) is a variable of \( B \), then \( \pi(v) \in T \), otherwise \( v \) is a variable in an “fr” atom and \( \pi(v) = \pi(v) \). This mapping is a homomorphism, thus we can consider the atomset \( F'' \) of \( F \), defined as follows: if \( v \) is a variable of \( B \), such that \( \pi(v) \in T \) and \( \pi(v) = \pi(v) \), where \( T \) is the variable of \( H \) that produced \( \pi(v) \), otherwise \( \pi(v) = \pi(v) \). This mapping is a homomorphism. This homomorphism is new since it maps \( \pi'' \) to \( \pi'' \) (h). Thus, there is a piece-unifier of \( B \), with the head of \( R'' \) that unifies \( h \) and \( b \).

It remains now to prove that for each atom \( fr(t) \) in the body of \( R'' \) there exists a triggering path \( P_i = (R_i, \pi_i) = (R_i, \pi_i) \). Let \( t \) be a variable occurring in some \( fr \) atom in \( R'' \). Suppose that \( fr(t) \) does not appear in any agglomerated rule corresponding to a triggering path \( P_i \) between \( (R_i, \pi_i) \) and \( (R_n, \pi_n) \). Since \( \pi(t) \) is an existential variable generated by the application of \( R \), and there is no unifier on the GRD paths that correspond to these triggering paths that unify \( t \), \( \pi(t) \) may only occur in atoms that are not used (even transitively) by \( (R_n, \pi_n) \), i.e., \( \pi(t) \notin T' \). Therefore, \( t \) does not appear in a \( fr \) atom \( R'' \), leading to a contradiction.

Since \( R'' \) and \( R'' = \bigcup R'' \) have the same head and the frontier of \( R'' \) is a subset of the frontier of \( R'' \) any unifier with \( R'' \) is also a unifier with \( R'' \). Thus, there is a unifier of \( R \), with \( R'' \) that unifies \( h \) and \( b \) and there are the corresponding correct transition edges in \( PG'' \).

Proof: (Theorem 1)

Let us say that a transition edge from \([a, i] \) in \( R \) to \([a', i] \) in \( R' \) is useful if there is a fact \( F \), and a homomorphism \( \pi \) from \( B \) to \( F \), such that there is a homomorphism \( \pi' \) from \( B' \) to some \( F' \) obtained from \( P \) and \( \pi'(a) = \pi(a) \). Furthermore, we say that the application of \( R \) uses edge \( ([a, i], [a', i]) \).

One can see that a useful edge exactly corresponds to a \( h \to b \) triggering sequence where \([a, i] \) occurs in \( h \) and \([a', i] \) occurs in \( b \). It follows from the correctness of \( PG'' \) that \( PG'' \) has a useful edge if \( PG'' \) is removed.

Now, let \( Y \) be a cyclicity proposition ensuring the halting of some change variant \( C \). Assume there is a set of rules \( R \) that satisfies \( Y \) but not \( Y' \) and there is \( F \) such that the \( C \)-change does not halt on \( (F, R') \). Then, there is a rule application in \( (F, R') \) that uses a transition edge \([a, i], [a', i] \) belonging to \( Y'' \) but not \( Y'' \). It is impossible because such an edge is useful. The same arguments hold for \( Y'' \).

Theorem 4

Let \( Y \) be an cyclicity property, and \( R \) be a set of rules. If checking that \( R \) is \( Y \) is in \( \text{co-NP} \), then checking that \( R \) is \( Y'' \) or \( Y'' \) is \( \text{co-NP} \)-complete.

We first state a preliminary proposition.

Proposition 18

If there is a \( h \to b \) triggering derivation sequence (with \( h \in \text{head}(R) \) and \( b \in \text{body}(R) \)), then there exist a non-empty set of paths \( \mathcal{P} = \{P_1, \ldots, P_k\} \) from \( R \) in \( \text{GRD}(R) \) such that \( \sum_{1 \leq i \leq k} |P_i| \leq |R| \times |\text{terms}(\text{head}(R))| \) and a piece-unifier of \( B \) with the head of an agglomerated rule along \( \mathcal{P} \) that unifies \( h \) and \( b \).

Proof: The piece-unifier is entirely determined by the terms that are forced into the frontier by an “fr” atom. Hence, we need to consider at most one path for each term in \( H \). Moreover, each (directed) cycle in the GRD (that is of length at most \( |R| \) ) needs to be traversed at most \( |\text{terms}(H)| \) times, since going through such a cycle without creating a new frontier variable cannot create any new unifier. Hence, we need to consider only paths of polynomial length.

Proof: (of Theorem 5) One can a cycle in \( PG'' \) (or \( PG'' \) (R)) such that the property \( Y \) is not satisfied by this cycle. From the previous property, each edge of the cycle has a polynomial certificate, and checking if a given substitution is a piece-unifier can also be done in polynomial time. Since \( Y \) is in \( \text{co-NP} \), we have a polynomial certificate that this cycle does not satisfy \( Y \). Membership to \( \text{co-NP} \) follows.

The completeness part is proved by a simple reduction from the co-problem of rule dependency checking (which is thus a \( \text{co-NP} \)-complete problem).

Let \( R_1 \) and \( R_2 \) be two rules. We first define two fresh predicates \( p \) and \( s \) of arity \{vars\( (B_1) \} \) and two fresh predicates \( q \) and \( r \) of arity \{vars\( (B_2) \} \). We build \( R_0 = p(x) \rightarrow s(x) \) if \( x \) is a list of all variables in \( B_1 \), and \( R_2 = r(x) \rightarrow q(x) \), where \( x = (z, z', \ldots, z) \), where \( z \) is a variable which does not appear in \( B_2 \), and \( z' \) is a list of all variables in \( B_2 \). We rewrite \( R_1 \) into \( R_1' = (B_1, s(x) \rightarrow H_1) \), where \( x \) is a list of all variables in \( B_1 \), and \( R_2 \) into \( R_2' = (B_2, r(x) \rightarrow H_2) \), where \( x \) is a list of all variables in \( B_2 \). One can check that \( R = \{R_0, R_1', R_2', R_3\} \) contains a cycle going through an existential variable (thus, it is not \( waD \)) if \( R_2 \) depends on \( R_1 \).

Proposition 6

Let \( R_1 \) and \( R_2 \) be rules, and let \( \mu \) be a unifier of \( B_2 \) with \( H_1 \). If \( \mu \) is incomparable, then no application of \( R_2 \) can use an atom in \( \mu(H_1) \).

Proof: We first formalize the sentence “no application of \( R_2 \) can use an atom in \( \mu(H_1) \)” by the following sentence: “no application \( \nu \) of \( R_2 \) can map an atom \( a \in B_2 \) to an atom \( b \) produced by a production \( (R_1, \sigma) \) such that \( \nu(a) = \pi(b) \), where \( \pi, \sigma \) are more specific than \( \mu \) (given two substitutions \( \sigma_1 \) and \( \sigma_2 \), \( \sigma_1 \) is more specific than \( \sigma_2 \) if there is a substitution \( s \) such that \( \sigma_1 = s \circ \sigma_2 \)).

Consider the application of \( R_1 \) to a fact \( \sigma \), a homomorphism \( \pi \), followed by an application of \( R_2 \) w.r.t. a homomorphism \( \sigma' \), such that for an atom \( a \in B_2 \), \( \pi(a) = b = \pi(b) \), where \( \pi, \sigma \) are more specific than \( \mu \). Note that this implies that \( \mu(a) = \mu(b) \). Assume that \( b \) contains a fresh variable \( z' \) produced from an existential variable \( z \) in \( H_1 \). Let \( z' \) be the variable from \( a \) such that \( \pi'(z') = z_1 \). Since the domain of \( \pi' \) is \( B_2 \), all atoms from \( B_2 \) in which \( z' \) occurs at a given position \( p_j \) are also mapped by \( \pi' \) to atoms containing \( z_1 \) in the same position \( p_j \). Since \( z_1 \) is a fresh variable, these atoms have been produced by sequences of rule applications starting from \( (R_1, \pi) \). Such a sequence of rule applications exists only if there is a path in \( PG'' \) from a position \( z_1 \) in \( H_1 \); moreover, this path cannot go through an existential position, otherwise \( z_1 \) cannot be propagated. Hence, \( \mu \) is necessarily comparable.

Proposition 8

If, for each existential position \([a, i] \), all compatible cycles for \([a, i] \) in \( PG'' \) are self-blocking, then the stable computation based on the skolem chase halts.

Proof: If a cycle is non-compatible or self-blocking, then no sequence of rule applications can use it (where "used" is defined as
in the proof of Theorem\ref{thm:stable}. Hence, if all compatible cycles are self-blocking, all derivations obtained with skolemized NME rule applications are finite. Hence, the stable computation based on the skolem chase halts.

\[\square\]
